Moxa IA240 and IA241 are RISC-based ready-to-run embedded computers. Available features include four RS-232/422/485 serial ports, dual 10/100 Mbps Ethernet ports, PCMCIA, SD socket for storage expansion and USB 2.0 host making IA240/241 ideal for your embedded applications.

The following topics are covered in this chapter:

- **Overview**
- **Software Architecture**
  - Journaling Flash File System (JFFS2)
  - Software Package
Overview

The IA240/IA241 embedded computers, which are designed for industrial automation applications, feature 4 RS-232/422/485 serial ports, dual Ethernet ports, 4 digital input channels, 4 digital output channels, and a PCMCIA cardbus and SD socket. The computers come in a compact, IP30 protected, industrial-strength rugged chassis. The DIN-Rail vertical form factor makes it easy to install the IA240/241 embedded computers in small cabinets. This space-saving feature also facilitates easy wiring, and makes the IA240/241 the best choice as front-end embedded controllers for industrial applications.

In addition to the standard models, the IA240/IA241 also come in wide temperature models. The IA240-T and IA241-T have an operating temperature range of -40 to 75°C, and are appropriate for harsh industrial automation environments. The industrial mechanism of the IA240/IA241 design provides robust, reliable computing. Due to the RISC-based architecture, the IA240/IA241 will not generate a lot of heat when in use. The high communication performance and fanless design make the IA240/IA241 ideal for industrial automation environments.

The IA240/241 computers use a Moxa ART 192 Mhz RISC CPU. Unlike the X86 CPU, which uses a CISC design, the RISC architecture and modern semiconductor technology provide these embedded computers with a powerful computing engine and communication functions, but without generating a lot of heat. A 16 MB NOR Flash ROM and a 64 MB SDRAM give you enough memory to install your application software directly on the embedded computer. In addition, dual LAN ports are built right into the RISC CPU. This network capability, in combination with the ability to control serial devices, makes the IA240/241 ideal communication platforms for data acquisition and industrial control applications.

The IA240/241’s pre-installed Linux operating system (OS) provides an open software operating system for your software program development. Software written for desktop PCs can be easily ported to the computer with a GNU cross compiler, without needing to modify the source code. The OS, device drivers (e.g., serial and buzzer control), and your own applications, can all be stored in the NOR Flash memory.

The IA240/241 Linux Series (referred to here as IA240/241, or as the target computer) consists of two models: IA241-LX with CardBus, and IA240-LX (which doesn’t support CardBus). Both models have exactly the same hardware and software features, except for the PCMCIA CardBus provided by the IA241-LX.

Software Architecture

The Linux operating system that is pre-installed in the IA240/241 follows the standard Linux architecture, making it easy to accept programs that follow the POSIX standard. Program porting is done with the GNU Tool Chain provided by Moxa. In addition to Standard POSIX APIs, device drivers for the USB storage, buzzer and Network controls, and UART are also included in the Linux OS.
The IA240/241’s built-in Flash ROM is partitioned into **Boot Loader**, **Linux Kernel**, **Root File System**, and **User directory** partitions.

In order to prevent user applications from crashing the Root File System, the IA240/241 uses a specially designed **Root File System with Protected Configuration** for emergency use. This **Root File System** comes with serial and Ethernet communication capability for users to load the **Factory Default Image** file. The user directory saves the user’s settings and application.

To improve system reliability, the IA240/241 has a built-in mechanism that prevents the system from crashing. When the Linux kernel boots up, the kernel will mount the root file system for read only, and then enable services and daemons. During this time, the kernel will start searching for system configuration parameters via `rc` or `inittab`.

Normally, the kernel uses the Root File System to boot up the system. The Root File System is protected, and cannot be changed by the user. This type of setup creates a “safe” zone.

For more information about the memory map and programming, refer to Chapter 5, *Programmer’s Guide*.

### Journaling Flash File System (JFFS2)

The Root File System and User directory in the flash memory is formatted with the **Journaling Flash File System (JFFS2)**. The formatting process places a compressed file system in the flash memory. This operation is transparent to the user.

The Journaling Flash File System (JFFS2), which was developed by Axis Communications in Sweden, puts a file system directly on the flash, instead of emulating a block device. It is designed for use on flash-ROM chips and recognizes the special write requirements of a flash-ROM chip. JFFS2 implements wear-leveling to extend the life of the flash disk, and stores the flash directory structure in the RAM. A log-structured file system is maintained at all times. The system is always consistent, even if it encounters crashes or improper power-downs, and does not require `fsck` (file system check) on boot-up.

JFFS2 is the newest version of JFFS. It provides improved wear-leveling and garbage-collection performance, improved RAM footprint and response to system-memory pressure, improved concurrency and support for suspending flash erases, marking of bad sectors with continued use of the remaining good sectors (enhancing the write-life of the devices), native data compression inside the file system design, and support for hard links.
The key features of JFFS2 are:

- Targets the Flash ROM Directly
- Robustness
- Consistency across power failures
- No integrity scan (fsck) is required at boot time after normal or abnormal shutdown
- Explicit wear leveling
- Transparent compression

Although JFFS2 is a journaling file system, this does not preclude the loss of data. The file system will remain in a consistent state across power failures and will always be mountable. However, if the board is powered down during a write then the incomplete write will be rolled back on the next boot, but writes that have already been completed will not be affected.

Additional information about JFFS2 is available at:
http://developer.axis.com/software/jffs/
http://www.linux-mtd.infradead.org/

Software Package

- Debuggers and tools:
  - GDB (V5.3): Source Level Debug Server
  - Glibc (V2.2.5): POSIX standard C library
In this chapter, we explain how to connect the IA240/241, how to turn on the power, how to get started programming, and how to use the IA240/241’s other functions.

The following topics are covered in this chapter:

- **Powering on the IA240/241**
- **Connecting the IA240/241 to a PC**
  - Serial Console
  - Telnet Console
  - SSH Console
- **Configuring the Ethernet Interface**
  - Modifying Network Settings with the Serial Console
  - Modifying Network Settings over the Network
- **Configuring the WLAN via the PCMCIA Interface**
  - IEEE802.11g
- **SD Socket and USB for Storage Expansion**
- **Test Program—Developing Hello.c**
  - Installing the Tool Chain (Linux)
  - Checking the Flash Memory Space
  - Compiling Hello.c
  - Uploading and Running the “Hello” Program
- **Developing Your First Application**
  - Testing Environment
  - Compiling tcp2.c
  - Uploading and Running the “tcp2-release” Program
  - Testing Procedure Summary
Powering on the IA240/241

Connect the SG wire to the shielded contact located in the upper left corner of the IA240/241, and then power on the computer by connecting it to the power adaptor. It takes about 30 to 60 seconds for the system to boot up. Once the system is ready, the Ready LED will light up.

**NOTE**

After connecting the IA240/241 to the power supply, it will take about 30 to 60 seconds for the operating system to boot up. The green Ready LED will not turn on until the operating system is ready.

**ATTENTION**

This product is intended to be supplied by a Listed Power Unit and output marked with “LPS” and rated 12-48 VDC, 580 mA (minimum requirements).

Connecting the IA240/241 to a PC

There are two ways to connect the IA240/241 to a PC: through the Serial Console port or via Telnet over the network.

**Serial Console**

The serial console port gives users a convenient way of connecting to the IA240/241’s console utility. This method is particularly useful when using the computer for the first time. The signal is transmitted over a direct serial connection, so you do not need to know either of its two IP addresses in order to connect to the serial console utility.

Use the serial console port settings shown below.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Baudrate</td>
<td>115200 bps</td>
</tr>
<tr>
<td>Parity</td>
<td>None</td>
</tr>
<tr>
<td>Data bits</td>
<td>8</td>
</tr>
<tr>
<td>Stop bits:</td>
<td>1</td>
</tr>
<tr>
<td>Flow Control</td>
<td>None</td>
</tr>
<tr>
<td>Terminal</td>
<td>VT100</td>
</tr>
</tbody>
</table>

Once the connection is established, the following window will open.
To log in, type the Login name and password as requested. The default values are both root:

Login: root
Password: root

Telnet Console

If you know at least one of the two IP addresses and netmasks, then you can use Telnet to connect to the IA240/241’s console utility. The default IP address and Netmask for each of the two ports are given below:

<table>
<thead>
<tr>
<th></th>
<th>Default IP Address</th>
<th>Netmask</th>
</tr>
</thead>
<tbody>
<tr>
<td>LAN 1</td>
<td>192.168.3.127</td>
<td>255.255.255.0</td>
</tr>
<tr>
<td>LAN 2</td>
<td>192.168.4.127</td>
<td>255.255.255.0</td>
</tr>
</tbody>
</table>

Use a cross-over Ethernet cable to connect directly from your PC to the IA240/241. You should first modify your PC’s IP address and netmask so that your PC is on the same subnet as one of IA240/241’s two LAN ports. For example, if you connect to LAN 1, you can set your PC’s IP address to 192.168.3.126 and netmask to 255.255.255.0. If you connect to LAN 2, you can set your PC’s IP address to 192.168.4.126 and netmask to 255.255.255.0.

To connect to a hub or switch connected to your local LAN, use a straight-through Ethernet cable. The default IP addresses and netmasks are shown above. To login, type the Login name and password as requested. The default values are both root:

Login: root
Password: root
You can proceed with configuring the network settings of the target computer when you reach the bash command shell. Configuration instructions are given in the next section.

**ATTENTION**

**Serial Console Reminder**

Remember to choose VT100 as the terminal type. Use the cable CBL-RJ45F9-150, which comes with the IA240/241, to connect to the serial console port.

**Telnet Reminder**

When connecting to the IA240/241 over a LAN, you must configure your PC’s Ethernet IP address to be on the same subnet as the IA240/241 that you wish to contact. If you do not get connected on the first try, re-check the serial and IP settings, and then unplug and re-plug the IA240/241’s power cord.

**SSH Console**

The IA240/241 supports an SSH Console to provide users with better security options.

**Windows Users**

Click on the link http://www.chiark.greenend.org.uk/~sgtatham/putty/download.html to download PuTTY (free software) to set up an SSH console for the IA240/241 in a Windows environment. The following figure shows a simple example of the configuration that is required.
Linux Users

From a Linux machine, use the “ssh” command to access the IA240/241’s console utility via SSH.

```bash
#ssh 192.168.3.127
```

Select yes to complete the connection.

```
[root@bee_notebook root]# ssh 192.168.3.127
The authenticity of host '192.168.3.127 (192.168.3.127)' can't be established.
Are you sure you want to continue connection (yes/no)? yes
```

**NOTE**  
SSH provides better security compared to Telnet for accessing the IA240/241’s console utility over the network.
Configuring the Ethernet Interface

The network settings of the IA240/241 can be modified with the serial console, or online over the network.

Modifying Network Settings with the Serial Console

In this section, we use the serial console to configure the network settings of the target computer.

1. Follow the instructions given in a previous section to access the Console Utility of the target computer via the serial console port, and then type `# cd /etc/network` to change directories.

2. Type `# vi interfaces` to edit the network configuration file with vi editor. You can configure the Ethernet ports of the IA240/241 for static or dynamic (DHCP) IP addresses.

Static IP addresses:

As shown below, 4 network addresses must be modified: address, network, netmask, and broadcast. The default IP addresses are 192.168.3.127 for LAN1 and 192.168.4.127 for LAN2, with default netmask of 255.255.255.0.

```bash
# We always want the loopback interface.
auto eth0 eth1 lo
iface lo inet loopback

# embedded ethernet LAN1
iface eth0 inet static
    address 192.168.3.127
    network 192.168.3.0
    netmask 255.255.255.0
    broadcast 192.168.3.255

# embedded ethernet LAN2
iface eth1 inet static
    address 192.168.4.127
    network 192.168.4.0
    netmask 255.255.255.0
    broadcast 192.168.4.255

# 802.11g Gigabyte Cardbus wireless card
iface eth2 inet static
    address 192.168.5.127
    network 192.168.5.0
```

"/etc/network/interfaces" line 1 of 162 --0%--
Dynamic IP addresses:

By default, the IA240/241 is configured for “static” IP addresses. To configure one or both LAN ports to request an IP address dynamically, replace \texttt{static} with \texttt{dhcp} and then delete the address, network, netmask, and broadcast lines.

<table>
<thead>
<tr>
<th>Default Setting for LAN1</th>
<th>Dynamic Setting using DHCP</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{iface eth0 inet static}</td>
<td>\texttt{iface eth0 inet dhcp}</td>
</tr>
<tr>
<td>address 192.168.3.127</td>
<td></td>
</tr>
<tr>
<td>network: 192.168.3.0</td>
<td></td>
</tr>
<tr>
<td>netmask 255.255.255.0</td>
<td></td>
</tr>
<tr>
<td>broadcast 192.168.3.255</td>
<td></td>
</tr>
</tbody>
</table>

3. After the boot settings of the LAN interface have been modified, issue the following command to activate the LAN settings immediately:

\texttt{#/etc/init.d/networking restart}

\textbf{NOTE} After changing the IP settings, use the \texttt{networking restart} command to activate the new IP address.

Modifying Network Settings over the Network

IP settings can be activated over the network, but the new settings will not be saved to the flash ROM without modifying the file \texttt{/etc/network/interfaces}.

For example, type the command \texttt{#ifconfig eth0 192.168.1.1} to change the IP address of LAN1 to 192.168.1.1.

```
root@Moxa:~# ifconfig eth0 192.168.1.1
```

Configuring the WLAN via the PCMCIA Interface

IEEE802.11g

The following IEEE802.11g wireless card modules are supported:

- ASUS—WL-107g
- CNET—CWC-854 (181D version)
- Edmiax—EW-7108PCg
- Amigo—AWP-914W
- GigaByte—GN-WMKG
- Other brands that use the Ralink RT2500 series chip set

To configure the WLAN for IEEE802.11g:
1. Unplug the CardBus Wireless LAN card first.

2. Use the command `#vi /etc/networking/interfaces` to open the “interfaces” configuration file with vi editor, and then edit the 802.11g network settings (circled in red in the following figure).

3. Additional WLAN parameters are contained in the file `RT2500STA.dat`. To open the file, navigate to the RT2500STA folder and invoke vi, or type the command `#vi /etc/Wireless/RT2500STA/RT2500STA.dat` to edit the file with vi editor. Options for the various parameters are listed below the figure.
CountryRegion—Sets the channels for your particular country / region

SD Socket and USB for Storage Expansion

Both the IA240 and IA241 provide an SD socket for storage expansion. Moxa provides an SD flash disk for plug & play expansion that allows users to plug in a Secure Digital (SD) memory card compliant with the SD 1.0 standard for up to 1 GB of additional memory space, or a Secure Digital High Capacity (SDHC) memory card compliant with the SD 2.0 standard for up to 16 GB of additional memory space. The SD socket is located on the front panel of the IA240/241. To install an SD card, you must first remove the SD protection cover to access the socket, and then plug the SD card directly into the socket. Remember to press on the SD card first if you want to remove it.

The SD card will be mounted at `/mnt/sd`.

In addition to the SD socket, a USB 2.0 host is located on the front panel. The USB host is also designed for storage expansion. To expand the storage by USB flash disk, you just need to plug the USB flash disk into this USB port. The flash disk will be detected automatically, and its file partition will be mounted into the OS. The USB storage will be mounted at `/mnt/usbstorage`.

Test Program—Developing Hello.c

In this section, we use the standard “Hello” programming example to illustrate how to develop a program for the IA240/241. In general, program development involves the following seven steps.

**Step 1:**  
Connect the IA240/241 to a Linux PC.

**Step 2:**  
Install Tool Chain (GNU Cross Compiler & glibc).

**Step 3:**  
Set the cross compiler and glibc environment variables.

**Step 4:**  
Code and compile the program.

**Step 5:**  
Download the program to the IA240/241 Via FTP or NFS.

**Step 6:**  
Debug the program  
→ If bugs are found, return to Step 4.  
→ If no bugs are found, continue with Step 7.

**Step 7:**  
Back up the user directory (distribute the program to additional IA240/241 units if needed).
Installing the Tool Chain (Linux)

The Linux Operating System must be pre-installed in the PC before installing the IA240/241 GNU Tool Chain. Fedora core or compatible versions are recommended. The Tool Chain requires approximately 100 MB of hard disk space on your PC. The IA240/241 Tool Chain software is located on the IA240/241 CD. To install the Tool Chain, insert the CD into your PC and then issue the following commands:

```
# mount /dev/cdrom /mnt/cdrom
# sh /mnt/cdrom/tool-chain/linux/install.sh
```

The Tool Chain will be installed automatically on your Linux PC within a few minutes. Before compiling the program, be sure to set the following path first, since the Tool Chain files, including the compiler, link, library, and include files are located in this directory.

```
PATH=/usr/local/arm-linux/bin:$PATH
```

Setting the path allows you to run the compiler from any directory.

Checking the Flash Memory Space

If the flash memory is full, you will not be able to save data to the Flash ROM. Use the following command to calculate the amount of “Available” flash memory:

```
/>df -h
```

If there isn’t enough “Available” space for your application, you will need to delete some existing files. To do this, connect your PC to the IA240/241 with the console cable, and then use the console utility to delete the files from the IA240/241’s flash memory. To check the amount of free space available, look at the directories in the read/write directory `/dev/mtdblock3`. Note that the directories `/home` and `/etc` are both mounted on the directory `/dev/mtdblock3`.

**NOTE**

If the flash memory is full, you will need to free up some memory space before saving files to the Flash ROM.

Compiling Hello.c

The package CD contains several example programs. Here we use Hello.c as an example to show you how to compile and run your applications. Type the following commands from your PC to copy the files used for this example from the CD to your computer’s hard drive:

```
# cd /tmp/
# mkdir example
```
To compile the program, go to the Hello subdirectory and issue the following commands:

```
# cd example/hello
# make
```

You should receive the following response:

```
[root@localhost hello]# make
/usr/local/arm-linux/bin/arm-linux-gcc -o hello-release hello.c
/usr/local/arm-linux/bin/arm-linux-strip -s hello-release
/usr/local/arm-linux/bin/arm-linux-gcc -ggdb -o hello-debug hello.c
[root@localhost hello]# 
```

Next, execute hello.exe to generate hello-release and hello-debug, which are described below:

- **hello-release**—an ARM platform execution file (created specifically to run on the IA240/241)
- **hello-debug**—an ARM platform GDB debug server execution file (see Chapter 5 for details about the GDB debug tool).

**NOTE**

Since Moxa’s tool chain places a specially designed Makefile in the directory /tmp/example/hello, be sure to type the `make` command from within that directory. This special Makefile uses the mxscale-gcc compiler to compile the hello.c source code for the Xscale environment. If you type the `make` command from within any other directory, Linux will use the x86 compiler (for example, cc or gcc).

Refer to Chapter 5 to see a Makefile example.

**Uploading and Running the “Hello” Program**

Use the following commands to upload hello-release to the IA240/241 via FTP.

1. From the PC, type:
   ```
   #ftp 192.168.3.127
   ```

2. Use the bin command to set the transfer mode to Binary mode, and then use the put command to initiate the file transfer:
   ```
   ftp> bin
   ftp> put hello-release
   ```

3. From the IA240/241, type:
   ```
   # chmod +x hello-release
   # ./hello-release
   ```

The word Hello will be printed on the screen.

**Developing Your First Application**

We use the tcps2 example to illustrate how to build an application. The procedure outlined in the following subsections will show you how to build a TCP server program plus serial port communication that runs on the IA240/241.
Testing Environment

The tcps2 example demonstrates a simple application program that delivers transparent, bi-directional data transmission between the IA240/241’s serial and Ethernet ports. As illustrated in the following figure, the purpose of this application is to transfer data between PC 1 and the IA240/241 via an RS-232 connection. At the remote site, data can be transferred between the IA240/241’s Ethernet port and PC 2 over an Ethernet connection.

Compiling tcps2.c

The source code for the tcps2 example is located on the CD-ROM at CD-ROM://example/TCPServer2/tcps2.c. Use the following commands to copy the file to a specific directory on your PC. We use the directory /home/ia240241/1st_application/. Note that you need to copy 3 files—Makefile, tcps2.c, tcpsp.c—from the CD-ROM to the target directory.

```
#mount -t iso9660 /dev/cdrom /mnt/cdrom
#cp /mnt/cdrom/example/TCPServer2/tcps2.c /home/ia240241/1st_application/tcps2.c
#cp /mnt/cdrom/example/TCPServer2/tcpsp.c /home/ia240241/1st_application/tcpsp.c
#cp /mnt/cdrom/example/TCPServer2/Makefile.c /home/ia240241/1st_application/Makefile
```

Type `make` to compile the example code:

You will get the following response, indicating that the example program was compiled successfully.

```
root@server11:/home/ia240241/1st_application
```
Two executable files, tcps2-release and tcps2-debug, are created.

**tcps2-release**—an ARM platform execution file (created specifically to run on the IA240/241)

**tcps2-debug**—an ARM platform GDB debug server execution file (see Chapter 5 for details about the GDB debug tool).

NOTE

If you get an error message at this point, it could be because you neglected to put tcps2.c and tcpsp.c in the same directory. The example Makefile we provide is set up to compile both tcps2 and tcpsp into the same project Makefile. Alternatively, you could modify the Makefile to suit your particular requirements.

Uploading and Running the “tcps2-release” Program

Use the following commands to use FTP to upload **tcps2-release** to the IA240/241.

1. From the PC, type:

```
#ftp 192.168.3.127
```

2. Next, use the **bin** command to set the transfer mode to **Binary**, and the **put** command to initiate the file transfer:

```
ftp> bin
ftp> put tcps2-release
```
3. From the IA240/241, type:

```
# chmod +x tcps2-release
# ./tcps2-release &
```
4. The program should start running in the background. Use the `#ps -ef` command to check if the tcp2 program is actually running in the background.

`#ps // use this command to check if the program is running`

```
192.168.3.127 - PuTTY
root@Moxa:~# ls -al
drwxr-xr-x 2 root root 0 Jun 12 02:14
drwxr-xr-x 15 root root 0 Jan 1 1970
-rw------- 1 root root 899 Jun 10 08:11 .bash_history
-rw------- 1 root root 4996 Jun 12 02:15 tcps2-release
root@Moxa:~# chmod +x tcps2-release
root@Moxa:~# ls -al
drwxr-xr-x 2 root root 0 Jun 12 02:14
drwxr-xr-x 15 root root 0 Jan 1 1970
-rw------- 1 root root 899 Jun 10 08:11 .bash_history
-rw------- 1 root root 4996 Jun 12 02:15 tcps2-release
root@Moxa:~# ./tcps2-release &
[1] 187
start
root@Moxa:~# ps
[1]+ Running ./tcps2-release &
root@Moxa:~#`
```

**NOTE**

Use the `kill` command for job number 1 to terminate this program: `#kill %1`

```
#ps -ef // use this command to check if the program is running
192.168.3.127 - PuTTY
[1]+ Running ./tcps2-release &
```
NOTE Use the `kill -9` command for PID 187 to terminate this program: `#kill -9 %187`

Testing Procedure Summary

1. Compile `tcps2.c` (`#make`).
2. Upload and run `tcps2-release` in the background (`#./tcps2-release &`).
3. Check that the process is running (`#jobs` or `#ps -ef`).
4. Use a serial cable to connect PC1 to the IA240/241’s serial port 1.
5. Use an Ethernet cable to connect PC2 to the IA240/241.
6. On PC1: If running Windows, use HyperTerminal (38400, n, 8, 1) to open COMn.
7. On PC2: Type `#telnet 192.168.3.127 4001`.
8. On PC1: Type some text on the keyboard and then press `Enter`.
9. On PC2: The text you typed on PC1 will appear on PC2’s screen.

The testing environment is illustrated in the following figure. However, note that there are limitations to the example program `tcps2.c`.

NOTE The `tcps2.c` application is a simple example designed to give users a basic understanding of the concepts involved in combining Ethernet communication and serial port communication. However, the example program has some limitations that make it unsuitable for real-life applications.

1. The serial port is in canonical mode and block mode, making it impossible to send data from the Ethernet side to the serial side (i.e., from PC 2 to PC 1 in the above example).
2. The Ethernet side will not accept multiple connections.
This chapter includes information about version control, deployment, updates, and peripherals. The information in this chapter will be particularly useful when you need to run the same application on several IA240/241 units.

The following topics are covered in this chapter:

- System Version Information
- System Image Backup
  - Upgrading the Firmware
  - Loading Factory Defaults
- Enabling and Disabling Daemons
- Setting the Run-Level
- Adjusting the System Time
  - Setting the Time Manually
  - NTP Client
  - Updating the Time Automatically
- Cron—Daemon to Execute Scheduled Commands
System Version Information

To determine the hardware capability of your IA240/241, and what kind of software functions are supported, check the version numbers of your IA240/241’s hardware, kernel, and user file system. Contact Moxa to determine the hardware version. You will need the Production S/N (Serial number), which is located on the IA240/241’s bottom label.

To check the kernel version, type:

```
# kversion
```

![Output of kversion command]

**NOTE**
The kernel version number is for the factory default configuration, and if you download the latest firmware version from Moxa’s website and then upgrade the IA240/241’s hardware.

System Image Backup

Upgrading the Firmware

The IA240/241’s bios, kernel, and root file system are combined into one firmware file, which can be downloaded from Moxa’s website (www.moxa.com). The name of the file has the form `ia240-x.x.x.frm` or `ia241-x.x.x.frm`, with “x.x.x” indicating the firmware version. To upgrade the firmware, download the firmware file to a PC, and then transfer the file to the IA240/241 via a serial Console or Telnet Console connection.

**ATTENTION**

Upgrading the firmware will erase all data on the Flash ROM

If you are using the `ramdisk` to store code for your applications, beware that updating the firmware will erase all of the data on the Flash ROM. You should back up your application files and data before updating the firmware.
Since different Flash disks have different sizes, it’s a good idea to check the size of your Flash disk before upgrading the firmware, or before using the disk to store your application and data files. Use the `# df -h` command to list the size of each memory block and how much free space is available in each block.

```
192.168.3.127 - PuTTY
root@Moxa:~# df -h
Filesystem     Size  Used Available Use% Mounted on
/dev/mtdblock2  8.0M   6.0M    2.0M   75% /
/dev/rm0       499.0k  16.0k   458.0k   3% /var
/dev/mtdblock3  6.0M  488.0k    5.5M    8% /tmp
/dev/mtdblock3  6.0M  488.0k    5.5M    8% /home
/dev/mtdblock3  6.0M  488.0k    5.5M    8% /etc
tmpfs           30.4M        0   30.4M    0% /dev/shm
root@Moxa:~# upramdisk
root@Moxa:~# df -h
Filesystem     Size  Used Available Use% Mounted on
/dev/mtdblock2  8.0M   6.0M    2.0M   75% /
/dev/rm0       499.0k  16.0k   458.0k   3% /var
/dev/mtdblock3  6.0M  488.0k    5.5M    8% /tmp
/dev/mtdblock3  6.0M  488.0k    5.5M    8% /home
/dev/mtdblock3  6.0M  488.0k    5.5M    8% /etc
tmpfs           30.4M        0   30.4M    0% /dev/shm
/dev/rm1       16.0M   1.0M  15.1M    0%  /mnt/ramdisk
root@Moxa:~# cd /mnt/ramdisk
root@Moxa:/mnt/ramdisk#
```

The following instructions give the steps required to save the firmware file to the IA240/241’s RAM disk and how to upgrade the firmware.

1. Type the following commands to enable the RAM disk:

   ```bash
   # upramdisk
   # cd /mnt/ramdisk
   ```

2. Type the following commands to use the IA240/241’s built-in FTP client to transfer the firmware file (`ia240-x.x.x.frm` or `ia241-x.x.x.frm`) from the PC to the IA240/241:

   ```bash
   /mnt/ramdisk> ftp <destination PC’s IP>
   Login Name: xxxx
   Login Password: xxxx
   ftp> bin
   ftp> get ia240-x.x.x.frm
   ```

```
192.168.3.127 - PuTTY
root@Moxa:/mnt/ramdisk# ftp 192.168.3.193
Connected to 192.168.3.193 (192.168.3.193).
220 TYPSoft FTP Server 1.10 ready...
Name (192.168.3.193:root): root
331 Password required for root.
Password: 
230 User root logged in.
Remote system type is UNIX.
Using binary mode to transfer files.
ftp> cd newsw
250 CWD command successful. "/C:/ftp/ftp/user/newsw/" is current directory.
ftp> bin
200 Type set to I.
ftp> ls
200 Port command successful.
150 Opening data connection for directory list.
drw-rw-rw- 1 ftp ftp 0 Nov 30 10:03.
drw-rw-rw- 1 ftp ftp 0 Nov 30 10:03.
-rw-rw-rw- 1 ftp ftp 13167772 Nov 29 10:24 ia240-1.0.frm
226 Transfer complete.
```
3. Next, use the **upfirm** command to upgrade the kernel and root file system:

   ```
   #upfirm ia240-1.0.frm
   ```

   ![Command output]

   **ATTENTION**

   The upfirm utility will reboot your target after the upgrade is OK.

**Loading Factory Defaults**

To load the factory default settings, you must press the reset-to-default button for more than 5 seconds. All files in the `/home` & `/etc` directories will be destroyed. Note that while pressing the reset-to-default button, the Ready LED will blink once every second for the first 5 seconds. The Ready LED will turn off after 5 seconds, and the factory defaults will be loaded.
Enabling and Disabling Daemons

The following daemons are enabled when the IA240/241 boots up for the first time.

- **snmpd** .......... SNMP Agent daemon
- **telnetd** .......... Telnet Server / Client daemon
- **inetd** ............. Internet Daemons
- **ftpd** ............ FTP Server / Client daemon
- **sshd** .......... Secure Shell Server daemon
- **httpd** .......... Apache WWW Server daemon

Type the command “ps -ef” to list all processes currently running.

```
root@Moxa:~# cd /etc
root@Moxa:/etc# ps -ef
```

To run a private daemon, you can edit the file rc.local, as follows:
```
#cd /etc/rc.d
#vi rc.local
```

Next, use vi to open your application program. We use the example program tcps2-release, and put it to run in the background.
```
#!/bin/sh
# Add you want to run daemon
/root/tcps2-release &~
```

To run a private daemon, you can edit the file rc.local, as follows:
```
#cd /etc/rc.d
#vi rc.local
```

Next, use vi to open your application program. We use the example program tcps2-release, and put it to run in the background.
```
#!/bin/sh
# Add you want to run daemon
/root/tcps2-release &~
```
The enabled daemons will be available after you reboot the system.

```
192.168.3.127 - PuTTY

root@Moxa:~#
```

**Setting the Run-Level**

In this section, we outline the steps you should take to set the Linux run-level and execute requests. Use the following command to enable or disable settings:

```
#cd /etc/rc.d/init.d
#Edit a shell script to execute /root/tcp2s-release and save to tcp2s as an example.
#ln -s /etc/rc.d/init.d/tcp2s S60tcp2s
```

SxxRUNFILE stands for
S: start the run file while linux boots up.
xx: a number between 00-99. Smaller numbers have a higher priority.
RUNFILE: the file name.
KxxRUNFILE stands for
K: start the run file while linux shuts down or halts.
xx: a number between 00-99. Smaller numbers have a higher priority.
RUNFILE: the file name.

To remove the daemon, remove the run file from the `/etc/rc.d/rc3.d` directory by using the following command:

```
#rm -f /etc/rc.d/rc3.d/S60tcps2
```

### Adjusting the System Time

#### Setting the Time Manually

The IA240/241 has two time settings. One is the system time, and the other is the RTC (Real Time Clock) time kept by the IA240/241’s hardware. Use the `#date` command to query the current system time or set a new system time. Use `#hwclock` to query the current RTC time or set a new RTC time.

Use the following command to query the system time:

```
#date
```

Use the following command to query the RTC time:

```
#hwclock
```

Use the following command to set the system time:

```
#date MMDDhhmmYYYY
```

- **MM** = Month
- **DD** = Date
- **hhmm** = hour and minute
- **YYYY** = Year

Use the following command to set the RTC time:

```
#hwclock -w
```

Write current system time to RTC

The following figure illustrates how to update the system time and set the RTC time.
NTP Client

The IA240/241 has a built-in NTP (Network Time Protocol) client that is used to initialize a time request to a remote NTP server. Use `#ntpdate <this client utility>` to update the system time.

```
#ntpdate time.stdtime.gov.tw
#hwclock --w
```

Visit [http://www.ntp.org](http://www.ntp.org) for more information about NTP and NTP server addresses.

NOTE

Before using the NTP client utility, check your IP and DNS settings to make sure that an Internet connection is available. Refer to Chapter 2 for instructions on how to configure the Ethernet interface, and see Chapter 4 for DNS setting information.

Updating the Time Automatically

In this subsection, we show how to use a shell script to update the time automatically.

Example shell script to update the system time periodically

```
#!/bin/sh
ntpdate time.nist.gov # You can use the time server’s ip address or domain name directly. If you use domain name, you must enable the domain client on the system by updating #/etc/resolv.conf file.
hwclock --systohc
sleep 100 # Updates every 100 seconds. The min. time is 100 seconds. Change # 100 to a larger number to update RTC less often.
```

Save the shell script using any file name. E.g., `fixtime`
How to run the shell script automatically when the kernel boots up

Copy the example shell script `fixtime` to directory `/etc/init.d`, and then use `chmod 755 fixtime` to change the shell script mode. Next, use vi editor to edit the file `/etc/inittab`. Add the following line to the bottom of the file:

```
ntp : 2345 : respawn : /etc/init.d/fixtime
```

Use the command `#init q` to re-init the kernel.

Cron—Daemon to Execute Scheduled Commands

Start Cron from the directory `/etc/rc.d/rc.local`. It will return immediately, so you don’t need to start it with ‘&’ to run in the background.

The Cron daemon will search `/etc/cron.d/crontab` for crontab files, which are named after accounts in `/etc/passwd`.

Cron wakes up every minute, and checks each command to see if it should be run in the current minute.

Modify the file `/etc/cron.d/crontab` to set up your scheduled applications. Crontab files have the following format:

```
<table>
<thead>
<tr>
<th>mm</th>
<th>h</th>
<th>dom</th>
<th>mon</th>
<th>dow</th>
<th>user</th>
<th>command</th>
</tr>
</thead>
<tbody>
<tr>
<td>min</td>
<td>hour</td>
<td>date</td>
<td>month</td>
<td>week</td>
<td>user</td>
<td>command</td>
</tr>
<tr>
<td>0-59</td>
<td>0-23</td>
<td>1-31</td>
<td>1-12</td>
<td>0-6 (0 is Sunday)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

The following example demonstrates how to use Cron.

**How to use cron to update the system time and RTC time every day at 8:00.**

**STEP1:** Write a shell script named `fixtime.sh` and save it to `/home/`.

```
#!/bin/sh
ntpdate time.nist.gov
hwclock –systohc
exit 0
```

**STEP2:** Change mode of `fixtime.sh`

```
#chmod 755 fixtime.sh
```

**STEP3:** Modify `/etc/cron.d/crontab` file to run `fixtime.sh` at 8:00 every day.

Add the following line to the end of crontab:

```
* 8 * * * root/home/fixtime.sh
```

**STEP4:** Enable the cron daemon manually.

```
#/etc/init.d/cron start
```

**STEP5:** Enable cron when the system boots up.

Add the following line in the file `/etc/init.d/rc.local`

```
#/etc/init.d/cron start
```
In this chapter, we explain how to configure the IA240/241’s various communication functions.

The following topics are covered in this chapter:

- Telnet / FTP
- DNS
- Web Service—Apache
- Install PHP for Apache Web Server
- IPTABLES
- NAT
  - NAT Example
  - Enabling NAT at Bootup
- Dial-up Service—PPP
- PPPoE
- NFS (Network File System)
  - Setting up the IA240/241 as an NFS Client
- Mail
- SNMP
- OpenVPN
**Telnet / FTP**

In addition to supporting Telnet client/server and FTP client/server, the IA240/241 also supports SSH and sftp client/server. To enable or disable the Telnet/ftp server, you first need to edit the file `/etc/inetd.conf`.

**Enabling the Telnet/ftp server**

The following example shows the default content of the file `/etc/inetd.conf`. The default is to enable the Telnet/ftp server:

```
discard dgram udp wait root /bin/discard
discard stream tcp nowait root /bin/discard
telnet stream tcp nowait root /bin/telnetd
tftp stream tcp nowait root /bin/ftpd -l
```

**Disabling the Telnet/ftp server**

Disable the daemon by typing `#` in front of the first character of the row to comment out the line.

**DNS**

The IA240/241 supports DNS client (but not DNS server). To set up DNS client, you need to edit three configuration files: `/etc/hosts`, `/etc/resolv.conf`, and `/etc/nsswitch.conf`.

**/etc/hosts**

This is the first file that the Linux system reads to resolve the host name and IP address.

**/etc/resolv.conf**

This is the most important file that you need to edit when using DNS for the other programs. For example, before you use `#ntptime time.nist.gov` to update the system time, you will need to add the DNS server address to the file. Ask your network administrator which DNS server address you should use. The DNS server’s IP address is specified with the “nameserver” command. For example, add the following line to `/etc/resolv.conf` if the DNS server’s IP address is 168.95.1.1:

```
nameserver 168.95.1.1
```

**/etc/nsswitch.conf**

This file defines the sequence to resolve the IP address by using `/etc/hosts` file or `/etc/resolv.conf`.

```
10.120.53.100 - PuTTY
```

```
root@Moxa:/etc# cat resolv.conf
#
# resolv.conf This file is the resolver configuration file
# See resolver(5).
#
#nameserver 192.168.1.16
nameserver 168.95.1.1
nameserver 140.115.1.31
nameserver 140.115.236.10
root@Moxa:/etc#
```

```
/etc/nsswitch.conf
This file defines the sequence to resolve the IP address by using /etc/hosts file or /etc/resolv.conf.
```
Web Service—Apache

The Apache web server’s main configuration file is `/etc/apache/conf/httpd.conf`, with the default homepage located at `/home/httpd/htdocs/index.html`. Save your own homepage to the following directory:

`/home/httpd/htdocs/`

Save your CGI page to the following directory:

`/home/httpd/cgi-bin/`

Before you modify the homepage, use a browser (such as Microsoft Internet Explore or Mozilla Firefox) from your PC to test if the Apache Web Server is working. Type the LAN1 IP address in the browser’s address box to open the homepage. E.g., if the default IP address is still active, type `http://192.168.3.127` in the address box.

To open the default CGI page, type `http://192.168.3.127/cgi-bin/test-cgi` in your browser’s address box.
To open the default CGI test script report page, type `http://192.168.3.127/cgi-bin/test-cgi` in your browser’s address box.
NOTE
The CGI function is enabled by default. If you want to disable the function, modify the file /etc/apache/conf/httpd.conf. When you develop your own CGI application, make sure your CGI file is executable.

Install PHP for Apache Web Server

This embedded computer supports the PHP option. However, since the PHP file is 3 MB, it is not installed by default. To install it yourself, first make sure there is enough free space (at least 3 MB) on your embedded flash ROM).

Step 1: Check that you have enough free space

To check that the /dev/mtdblock3 free space is greater than 3 MB.

Step 2: Type ‘upramdisk’ to get the free space ram disk to save the package.
Step 3: Download the PHP package from the CD-ROM. You can find the package in CD-ROM/target/php/php.tar.gz

```
192.168.3.127 - PuTTY

root@Moxa:/bin# cd /mnt/ramdisk
root@Moxa:/mnt/ramdisk# ftp 192.168.27.130
Connected to 192.168.27.130.
220 (vsFTPd 2.0.1)
Name (192.168.27.130:root): root
331 Please specify the password.
Password: 
230 Login successful.
Remote system type is UNIX.
Using binary mode to transfer files.
ftp> cd /tmp
250 Directory successfully changed.
ftp> bin
200 Switching to Binary mode.
ftp> get php.tar.gz
local: php.tar.gz remote: php.tar.gz
200 PORT command successful. Consider using PASV.
150 Opening BINARY mode data connection for php.tar.gz (1789032 bytes).
226 File send OK.
1789032 bytes received in 0.66 secs (2.6e+03 Kbytes/sec)
ftp>
```

Step 4: Unpack the package. To do this, type the command ‘tar xzvf php.tar.gz’

```
192.168.3.127 - PuTTY

root@Moxa:/mnt/ramdisk# tar xzvf php.tar.gz
envvars
envvars.old
httpd.conf
httpd.conf.old
install.sh
lib
lib/libmysqlclient.so.15
lib/libpng.so.2
lib/libmysqlclient.so.15.0.0
lib/libgd.so
lib/libxml2.so.2.6.22
lib/libgd.so.2.0.0
lib/libjpeg.so
lib/libxml2.so.2
lib/libgd.so.2
php
php/php.ini
phpinfo.php
root@Moxa:/mnt/ramdisk#
```

Step 5: Run ‘install.sh’ and select to install php

```
192.168.3.127 - PuTTY

root@Moxa:/mnt/ramdisk# ./install.sh
Press the number:
1. Install PHP package
2. Uninstall PHP package
3. Exit.
1
Start to install PHP. Please wait ...
Starting web server: apache.
PHP install sucess.
root@Moxa:/mnt/ramdisk#
```
Step 6: Test it. Use the browser to access http://192.168.3.127/phpinfo.php

If you want to uninstall PHP, follow steps 2 to 5 but select the uninstall option.

IPTABLES

IPTABLES is an administrative tool for setting up, maintaining, and inspecting the Linux kernel’s IP packet filter rule tables. Several different tables are defined, with each table containing built-in chains and user-defined chains.

Each chain is a list of rules that apply to a certain type of packet. Each rule specifies what to do with a matching packet. A rule (such as a jump to a user-defined chain in the same table) is called a “target.”

The IA240/241 supports 3 types of IPTABLES table: Filter tables, NAT tables, and Mangle tables:

A. **Filter Table**—includes three chains:
   - INPUT chain
   - OUTPUT chain
   - FORWARD chain
B. **NAT Table**—includes three chains:

- **PREROUTING chain**—transfers the destination IP address (DNAT)
- **POSTROUTING chain**—works after the routing process and before the Ethernet device process to transfer the source IP address (SNAT)
- **OUTPUT chain**—produces local packets

  sub-tables

  - **Source NAT (SNAT)**—changes the first source packet IP address
  - **Destination NAT (DNAT)**—changes the first destination packet IP address
  - **MASQUERADE**—a special form for SNAT. If one host can connect to Internet, then other computers that connect to this host can connect to the Internet when the computer does not have an actual IP address.
  - **REDIRECT**—a special form of DNAT that re-sends packets to a local host independent of the destination IP address.

C. **Mangle Table**—includes two chains

- **PREROUTING chain**—pre-processes packets before the routing process.
- **OUTPUT chain**—processes packets after the routing process.

  It has three extensions—TTL, MARK, TOS.
The following figure shows the IPTABLES hierarchy.

The IA240/241 supports the following sub-modules. Be sure to use the module that matches your application.

<table>
<thead>
<tr>
<th>Module</th>
<th>Function</th>
<th>Function</th>
<th>Function</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip_conntrack</td>
<td>ipt_MARK</td>

<td></td>
<td></td>
</tr>
<tr>
<td>ipt_LOG</td>
<td>ipt_ULOG</td>
<td>ipt_owner</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
NOTE
The IA240/241 does NOT support IPV6 and ipchains.

The basic syntax to enable and load an IPTABLES module is as follows:

```bash
# lsmod
# modprobe ip_tables
# modprobe iptable_filter
```

Use `lsmod` to check if the ip_tables module has already been loaded in the IA240/241. Use `modprobe` to insert and enable the module.

Use the following command to load the modules (iptables_filter, iptable_mangle, iptable_nat):

```bash
# modprobe iptable_filter
```

NOTE
IPTABLES plays the role of packet filtering or NAT. Take care when setting up the IPTABLES rules. If the rules are not correct, remote hosts that connect via a LAN or PPP may be denied access. We recommend using the Serial Console to set up the IPTABLES.

Click on the following links for more information about iptables.

http://www.linuxguruz.com/iptables/

Since the IPTABLES command is very complex, to illustrate the IPTABLES syntax we have divided our discussion of the various rules into three categories: **Observe and erase chain rules**, **Define policy rules**, and **Append or delete rules**.

Observe and erase chain rules

**Usage:**

```bash
# iptables [-t tables] [-L] [-n]
- t tables: Table to manipulate (default: ‘filter’); example: nat or filter.
- L [chain]: List all rules in selected chains. If no chain is selected, all chains are listed.
- n: Numeric output of addresses and ports.
```

```bash
# iptables [-t tables] [-FZX]
- F: Flush the selected chain (all the chains in the table if none is listed).
- X: Delete the specified user-defined chain.
- Z: Set the packet and byte counters in all chains to zero.
```

**Examples:**

```bash
# iptables -L -n
```

In this example, since we do not use the `-t` parameter, the system uses the default ‘filter’ table. Three chains are included: INPUT, OUTPUT, and FORWARD. INPUT chains are accepted automatically, and all connections are accepted without being filtered.

```bash
#iptables -F
#iptables -X
#iptables -Z
```
Define policy for chain rules

Usage:

```
# iptables [-t tables] [-P] [INPUT, OUTPUT, FORWARD, PREROUTING, OUTPUT, POSTROUTING]
[ACCEPT, DROP]
```

- `-P`: Set the policy for the chain to the given target.
- `INPUT`: For packets coming into the IA240/241.
- `OUTPUT`: For locally-generated packets.
- `FORWARD`: For packets routed out through the IA240/241.
- `PREROUTING`: To alter packets as soon as they come in.
- `POSTROUTING`: To alter packets as they are about to be sent out.

Examples:

```
#iptables –P INPUT DROP
#iptables –P OUTPUT ACCEPT
#iptables –P FORWARD ACCEPT
#iptables –t nat –P PREROUTING ACCEPT
#iptables –t nat –P OUTPUT ACCEPT
#iptables –t nat –P POSTROUTING ACCEPT
```

In this example, the policy accepts outgoing packets and denies incoming packets.

Append or delete rules:

Usage:

```
# iptables [-t table] [-A] [INPUT, OUTPUT, FORWARD] [-i interface] [-o interface]
```

- `-A`: Append one or more rules to the end of the selected chain.
- `-I`: Insert one or more rules in the selected chain as the given rule number.
- `-i`: Name of an interface via which a packet is going to be received.
- `-o`: Name of an interface via which a packet is going to be sent.
- `-p`: The protocol of the rule or of the packet to check.
- `-s`: Source address (network name, host name, network IP address, or plain IP address).
- `--sport`: Source port number.
- `-d`: Destination address.
- `--dport`: Destination port number.
- `-j`: Jump target. Specifies the target of the rules; i.e., how to handle matched packets. For example, `ACCEPT` the packet, `DROP` the packet, or `LOG` the packet.

Examples:

Example 1: Accept all packets from lo interface.
```
# iptables –A INPUT –i lo –j ACCEPT
```

Example 2: Accept TCP packets from 192.168.0.1.
```
# iptables –A INPUT –i eth0 –p tcp –s 192.168.0.1 –j ACCEPT
```

Example 3: Accept TCP packets from Class C network 192.168.1.0/24.
```
# iptables –A INPUT –i eth0 –p tcp –s 192.168.1.0/24 –j ACCEPT
```

Example 4: Drop TCP packets from 192.168.1.25.
```
# iptables –A INPUT –i eth0 –p tcp –s 192.168.1.25 –j DROP
```

Example 5: Drop TCP packets addressed for port 21.
```
# iptables –A INPUT –i eth0 –p tcp –dport 21 –j DROP
```

Example 6: Accept TCP packets from 192.168.0.24 to IA240/241’s port 137, 138, 139.
```
# iptables –A INPUT –i eth0 –p tcp –s 192.168.0.24 –dport 137:139 –j ACCEPT
```
Example 7: Log TCP packets that visit IA240/241’s port 25.
# iptables -A INPUT -i eth0 -p tcp --dport 25 -j LOG

Example 8: Drop all packets from MAC address 01:02:03:04:05:06.
# iptables -A INPUT -i eth0 -p all -m mac --mac-source 01:02:03:04:05:06 -j DROP

NOTE: In Example 8, remember to issue the command `modprobe ipt_mac` first to load module ipt_mac.

### NAT

NAT (Network Address Translation) protocol translates IP addresses used on one network to different IP addresses used on another network. One network is designated the inside network and the other is the outside network. Typically, the IA240/241 connects several devices on a network and maps local inside network addresses to one or more global outside IP addresses, and un-maps the global IP addresses on incoming packets back into local IP addresses.

**NOTE**
Click on the following link for more information about iptables and NAT: [http://www.netfilter.org/documentation/HOWTO/NAT-HOWTO.html](http://www.netfilter.org/documentation/HOWTO/NAT-HOWTO.html)

### NAT Example

The IP address of LAN1 is changed to 192.168.3.127 (you will need to load the module ipt_MASQUERADE):

1. `# echo 1 > /proc/sys/net/ipv4/ip_forward`
2. `# modprobe ip_tables`
3. `# modprobe iptable_filter`
4. `# modprobe ip_conntrack`
5. `# modprobe iptable_nat`
6. `# modprobe ipt_MASQUERADE`
7. `# iptables -t nat -A POSTROUTING -o eth0 -j SNAT --to-source 192.168.3.127`
8. `# iptables -t nat -A POSTROUTING -o eth0 -s 192.168.3.0/24 -j MASQUERADE`
Enabling NAT at Bootup

In most real world situations, you will want to use a simple shell script to enable NAT when the IA240/241 boots up. The following script is an example.

```bash
#!/bin/bash
# If you put this shell script in the /home/nat.sh
# Remember to chmod 744 /home/nat.sh
# Edit the rc.local file to make this shell startup automatically.
# vi /etc/rc.d/rc.local
# Add a line in the end of rc.local /home/nat.sh
EXIF='eth0'  #This is an external interface for setting up a valid IP address.
EXNET='192.168.4.0/24'  #This is an internal network address.
# Step 1. Insert modules.
# Here 2> /dev/null means the standard error messages will be dump to null device.
modprobe ip_tables 2> /dev/null
modprobe ip_nat_ftp 2> /dev/null
modprobe ip_nat_irc 2> /dev/null
modprobe ip_conntrack 2> /dev/null
modprobe ip_conntrack_ftp 2> /dev/null
modprobe ip_conntrack_irc 2> /dev/null
# Step 2. Define variables, enable routing and erase default rules.
PATH=/bin:/sbin:/usr/bin:/usr/sbin:/usr/local/bin:/usr/local/sbin
export PATH
exif "1" > /proc/sys/net/ipv4/ip_forward
/bin/iptables -F
/bin/iptables -X
/bin/iptables -Z
/bin/iptables -F -t nat
/bin/iptables -X -t nat
/bin/iptables -Z -t nat
/bin/iptables -P INPUT ACCEPT
/bin/iptables -P OUTPUT ACCEPT
/bin/iptables -P FORWARD ACCEPT
/bin/iptables -t nat -P PREROUTING ACCEPT
/bin/iptables -t nat -P POSTROUTING ACCEPT
/bin/iptables -t nat -P OUTPUT ACCEPT
# Step 3. Enable IP masquerade.
```

Dial-up Service—PPP

PPP (Point to Point Protocol) is used to run IP (Internet Protocol) and other network protocols over a serial link. PPP can be used for direct serial connections (using a null-modem cable) over a Telnet link, and links established using a modem over a telephone line.

Modem / PPP access is almost identical to connecting directly to a network through the IA240/241’s Ethernet port. Since PPP is a peer-to-peer system, the IA240/241 can also use PPP to link two networks (or a local network to the Internet) to create a Wide Area Network (WAN).

NOTE

Click on the following links for more information about ppp:

http://tldp.org/HOWTO/PPP-HOWTO/index.html
http://axion.physics.ubc.ca/ppp-linux.html

The pppd daemon is used to connect to a PPP server from a Linux system. For detailed information about pppd see the man page.
Example 1: Connecting to a PPP server over a simple dial-up connection

The following command is used to connect to a PPP server by modem. Use this command for old ppp servers that prompt for a login name (replace \texttt{username} with the correct name) and password (replace \texttt{password} with the correct password). Note that \texttt{debug} and \texttt{defaultroute 192.1.1.17} are optional.

\begin{verbatim}
# pppd connect `chat -v " " ATDT5551212 CONNECT" " ogin: username word: password'
/dev/ttyM0 115200 debug crtscts modem defaultroute
\end{verbatim}

If the PPP server does not prompt for the username and password, the command should be entered as follows. Replace \texttt{username} with the correct username and replace \texttt{password} with the correct password.

\begin{verbatim}
# pppd connect `chat -v " " ATDT5551212 CONNECT" " ' user username password password
/dev/ttyM0 115200 crtscts modem
\end{verbatim}

The pppd options are described below:

\begin{itemize}
\item \texttt{connect `chat etc...'}
\item \texttt{-v}
\item \texttt{Double quotes—don’t wait for a prompt, but instead do ... (note that you must include a space after the second quotation mark)}
\item \texttt{ATDT5551212}
\item \texttt{Dial the modem, and then ...}
\item \texttt{CONNECT}
\item \texttt{Wait for an answer.}
\item \texttt{\ "}
\item \texttt{Send a return (null text followed by the usual return)}
\item \texttt{ogin: username word: password}
\item \texttt{Log in with \texttt{username} and \texttt{password}}.
\end{itemize}

Refer to the chat man page, chat.8, for more information about the chat utility.

\begin{verbatim}
/dev/
\end{verbatim}

Specify the callout serial port.

\begin{verbatim}
115200
\end{verbatim}

The baudrate.

\begin{verbatim}
debug
\end{verbatim}

Log status in syslog.

\begin{verbatim}
crtscts
\end{verbatim}

Use hardware flow control between computer and modem (at 115200 this is a must).

\begin{verbatim}
modem
\end{verbatim}

Indicates that this is a modem device; pppd will hang up the phone before and after making the call.

\begin{verbatim}
defaultroute
\end{verbatim}

Once the PPP link is established, make it the default route; if you have a PPP link to the Internet, this is probably what you want.
This is a degenerate case of a general option of the form x.x.x.x:y.y.y.y. Here x.x.x.x is the local IP address and y.y.y.y is the IP address of the remote end of the PPP connection. If this option is not specified, or if just one side is specified, then x.x.x.x defaults to the IP address associated with the local machine’s hostname (located in /etc/hosts), and y.y.y.y is determined by the remote machine.

Example 2: Connecting to a PPP server over a hard-wired link

If a username and password are not required, use the following command (note that noipdefault is optional):

```
#pppd connect 'chat -v " " " ' noipdefault /dev/ttyM0 19200 crtscts
```

If a username and password is required, use the following command (note that noipdefault is optional, and root is both the username and password):

```
#pppd connect 'chat -v " " " ' user root password root noipdefault
```

How to check the connection

Once you’ve set up a PPP connection, there are some steps you can take to test the connection. First, type:

```
/sbin/ifconfig
```

(The folder ifconfig may be located elsewhere, depending on your distribution.) You should be able to see all the network interfaces that are UP. ppp0 should be one of them, and you should recognize the first IP address as your own, and the “P-t-P address” (or point-to-point address) the address of your server. Here’s what it looks like on one machine:

```
lo    Link encap Local Loopback
      inet addr 127.0.0.1   Bcast 127.255.255.255   Mask 255.0.0.0
      UP LOOPBACK RUNNING   MTU 200   Metric 1
      RX packets 0 errors 0 dropped 0 overrun 0

ppp0   Link encap Point-to-Point Protocol
      inet addr 192.76.32.3   P-t-P 129.67.1.165   Mask 255.255.255.0
      UP POINTOPOINT RUNNING   MTU 1500   Metric 1
      RX packets 33 errors 0 dropped 0 overrun 0
      TX packets 42 errors 0 dropped 0 overrun 0
```

Now, type:

```
ping z.z.z.z
```

where z.z.z.z is the address of your name server. This should work. Here’s what the response could look like:

```
waddington:~$ ping 129.67.1.165
PING 129.67.1.165 (129.67.1.165): 56 data bytes
64 bytes from 129.67.1.165: icmp_seq=0 ttl=225 time=268 ms
64 bytes from 129.67.1.165: icmp_seq=1 ttl=225 time=247 ms
64 bytes from 129.67.1.165: icmp_seq=2 ttl=225 time=266 ms
^C
--- 129.67.1.165 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max = 247/260/268 ms
waddington:~$
Try typing:
```
netstat -nr
```

This should show three routes, something like this:

```
Kernel routing table
Destination Gateway Genmask Flags Metric Ref Use Interface
129.67.1.165 0.0.0.0 255.255.255.255 UH 0 0 6 ppp0
127.0.0.0 0.0.0.0 255.0.0.0 U 0 0 0 lo
0.0.0.0 129.67.1.165 0.0.0.0 UG 0 0 6298 ppp0
```

If your output looks similar but doesn’t have the destination 0.0.0.0 line (which refers to the default route used for connections), you may have run pppd without the ‘defaultroute’ option. At this point you can try using Telnet, ftp, or finger, bearing in mind that you’ll have to use numeric IP addresses unless you’ve set up /etc/resolv.conf correctly.

**Setting up a Machine for Incoming PPP Connections**

This first example applies to using a modem, and requiring authorization with a username and password.

```
pppd/dev/ttyM0 115200 crtscts modem 192.168.16.1:192.168.16.2 login auth
```

You should also add the following line to the file `/etc/ppp/pap-secrets`:

```plaintext
*    *    ""    *
```

The first star (*) lets everyone login. The second star (*) lets every host connect. The pair of double quotation marks (""") is to use the file `/etc/passwd` to check the password. The last star (*) is to let any IP connect.

The following example does not check the username and password:

```
pppd/dev/ttyM0 115200 crtscts modem 192.168.16.1:192.168.16.2
```

**PPPoE**

1. Connect IA240/241’s LAN port to an ADSL modem with a cross-over cable, HUB, or switch.
2. Login to the IA240/241 as the root user.
3. Edit the file `/etc/ppp/chap-secrets` and add the following:
   ```plaintext
   "username@hinet.net" "password"
   ```

   “`username@hinet.net`” is the username obtained from the ISP to log in to the ISP account.
   “`password`” is the corresponding password for the account.
4. Edit the file `/etc/ppp/pap-secrets` and add the following:

```
“username@hinet.net” * “password” *
```

“username@hinet.net” is the username obtained from the ISP to log in to the ISP account. “password” is the corresponding password for the account.

5. Edit the file `/etc/ppp/options` and add the following line:

```
plugin pppoe
```

6. Add one of two files: /etc/ppp/options.eth0 or /etc/ppp/options.eth1. The choice depends on which LAN is connected to the ADSL modem. If you use LAN1 to connect to the ADSL modem, then add /etc/ppp/options.eth0. If you use LAN2 to connect to the ADSL modem, then add /etc/ppp/options.eth1. The file context is shown below:

```
name username@inet.net
mtu 1492
mru 1492

defaultroute
noipdefault
```

Type your username (the one you set in the /etc/ppp/pap-secrets and /etc/ppp/chap-secrets files) after the “name” option. You may add other options as desired.

7. Set up DNS
   If you are using DNS servers supplied by your ISP, edit the file /etc/resolv.conf by adding the following lines of code:

   ```
   nameserver ip_addr_of_first_dns_server
   nameserver ip_addr_of_second_dns_server
   ```

   For example:
   ```
   nameserver 168.95.1.1
   nameserver 139.175.10.20
   ```

8. Use the following command to create a pppoe connection:
   ```
   pppd eth0
   ```
   The eth0 is what is connected to the ADSL modem LAN port. The example above uses LAN1.
   To use LAN2, type:
   ```
   pppd eth1
   ```

9. Type `ifconfig ppp0` to check if the connection is OK or has failed. If the connection is OK, you will see information about the ppp0 setting for the IP address. Use ping to test the IP.

10. If you want to disconnect it, use the kill command to kill the pppd process.
NFS (Network File System)

The Network File System (NFS) is used to mount a disk partition on a remote machine, as if it were on a local hard drive, allowing fast, seamless sharing of files across a network. NFS allows users to develop applications for the IA240/241, without worrying about the amount of disk space that will be available. The IA240/241 supports NFS protocol for client.

NOTE
Click on the following links for more information about NFS:
http://nfs.sourceforge.net/nfs-howto/client.html
http://nfs.sourceforge.net/nfs-howto/server.html

Setting up the IA240/241 as an NFS Client

The following procedure is used to mount a remote NFS Server.

1. To know the NFS Server’s shared directory.
2. Establish a mount point on the NFS Client site.
3. Mount the remote directory to a local directory.

```
#mkdir -p /home/nfs/public
#mount -t nfs NFS_Server(IP):/directory /mount/point
```

Example
```
#mount -t nfs 192.168.3.100:/home/public /home/nfs/public
```

Mail

smtpclient is a minimal SMTP client that takes an email message body and passes it on to an SMTP server. It is suitable for applications that use email to send alert messages or important logs to a specific user.

NOTE
Click on the following link for more information about smtpclient:
http://www.engelschall.com/sw/smtpclient/

To send an email message, use the ‘smtpclient’ utility, which uses SMTP protocol. Type `#smtpclient -help` to see the help message.

Example:
```
smtpclient -s test -f sender@company.com -S IP_address receiver@company.com < mail-body-message
```

- `s`: The mail subject.
- `f`: Sender’s mail address
- `S`: SMTP server IP address

The last mail address `receiver@company.com` is the receiver’s e-mail address. `mail-body-message` is the mail content. The last line of the body of the message should contain ONLY the period ‘.’ character.

You will need to add your hostname to the file `/etc/hosts`. 
SNMP

The IA240/241 has built-in SNMP V1 (Simple Network Management Protocol) agent software. It supports RFC1317 RS-232 like group and RFC 1213 MIB-II.

The following simple example allows you to use an SNMP browser on the host site to query the IA240/241, which is the SNMP agent. The IA240/241 will respond.

***** SNMP QUERY STARTED *****

→ IA240/241 does NOT support SNMP trap.

OpenVPN
OpenVPN provides two types of tunnels for users to implement VPNS: Routed IP Tunnels and Bridged Ethernet Tunnels. To begin with, check to make sure that the system has a virtual device /dev/net/tun. If not, issue the following command:

```
# mknod /dev/net/tun c 10 200
```

An Ethernet bridge is used to connect different Ethernet networks together. The Ethernets are bundled into one bigger, “logical” Ethernet. Each Ethernet corresponds to one physical interface (or port) that is connected to the bridge.

On each OpenVPN machine, you should generate a working directory, such as /etc/openvpn, where script files and key files reside. Once established, all operations will be performed in that directory.

Setup 1: Ethernet Bridging for Private Networks on Different Subnets

1. Set up four machines, as shown in the following diagram.

```
Host A (B) represents one of the machines that belongs to OpenVPN A (B). The two remote subnets are configured for a different range of IP addresses. When this setup is moved to a public network, the external interfaces of the OpenVPN machines should be configured for static IPs, or connect to another device (such as a firewall or DSL box) first.

```

```bash
# openvpn --genkey --secret secrouter.key
```

Copy the file that is generated to the OpenVPN machine.

2. Generate a script file named openvpn-bridge on each OpenVPN machine. This script reconfigures interface “eth1” as IP-less, creates logical bridge(s) and TAP interfaces, loads
#!/bin/sh

iface=eth1  # defines the internal interface
maxtap=`expr 1` # defines the number of tap devices. I.e., # of tunnels

IPADDR=
NETMASK=
BROADCAST=

# it is not a great idea but this system doesn’t support
# /etc/sysconfig/network-scripts/ifcfg-eth1
ifcfg_vpn() {

Create link symbols to enable this script at boot time:

# ln -s /etc/openvpn/openvpn-bridge /etc/rc.d/rc3.d/S32vpn-br # for example
# ln -s /etc/openvpn/openvpn-bridge /etc/rc.d/rc6.d/K32vpn-br # for example

3. Create a configuration file named A-tap0-br.conf and an executable script file named A-tap0-br.sh on OpenVPN A.

# point to the peer
remote 192.168.8.174
dev tap0
secret /etc/openvpn/secrouter.key
cipher DES-EDE3-CBC
auth MD5
tun-mtu 1500
tun-mtu-extra 64
ping 40
up /etc/openvpn/A-tap0-br.sh

#----------------------------------Start----------------------------
#!/bin/sh
# value after "-net" is the subnet behind the remote peer
route add -net 192.168.4.0 netmask 255.255.255.0 dev br0
#---------------------------------- end -----------------------------

Create a configuration file named B-tap0-br.conf and an executable script file named B-tap0-br.sh on OpenVPN B.

# point to the peer
remote 192.168.8.173
dev tap0
secret /etc/openvpn/secrouter.key
cipher DES-EDE3-CBC
auth MD5
tun-mtu 1500
tun-mtu-extra 64
ping 40
up /etc/openvpn/B-tap0-br.sh

#----------------------------------Start----------------------------
#!/bin/sh
# value after "-net" is the subnet behind the remote peer
route add -net 192.168.2.0 netmask 255.255.255.0 dev br0
#---------------------------------- end -----------------------------

Note: Select cipher and authentication algorithms by specifying “cipher” and “auth”. To see with algorithms are available, type:
4. Start both of OpenVPN peers,
   
   # openvpn --config A-tap0-br.conf&
   # openvpn --config B-tap0-br.conf&

   If you see the line “Peer Connection Initiated with 192.168.8.173:5000” on each machine, the
   connection between OpenVPN machines has been established successfully on UDP port 5000.

5. On each OpenVPN machine, check the routing table by typing the command:

   # route

<table>
<thead>
<tr>
<th>Destination</th>
<th>Gateway</th>
<th>Genmsk</th>
<th>Flags</th>
<th>Metric</th>
<th>Ref</th>
<th>Use</th>
<th>Iface</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.168.4.0</td>
<td>*</td>
<td>255.255.255.0</td>
<td>U</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>br0</td>
</tr>
<tr>
<td>192.168.2.0</td>
<td>*</td>
<td>255.255.255.0</td>
<td>U</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>br0</td>
</tr>
<tr>
<td>192.168.8.0</td>
<td>*</td>
<td>255.255.255.0</td>
<td>U</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>eth0</td>
</tr>
</tbody>
</table>

   Interface eth1 is connected to the bridging interface br0, to which device tap0 also connects,
   whereas the virtual device tun sits on top of tap0. This ensures that all traffic from internal
   networks connected to interface eth1 that come to this bridge write to the TAP/TUN device
   that the OpenVPN program monitors. Once the OpenVPN program detects traffic on the
   virtual device, it sends the traffic to its peer.

6. To create an indirect connection to Host B from Host A, you need to add the following routing
   item:

   route add –net 192.168.4.0 netmask 255.255.255.0 dev eth0

   To create an indirect connection to Host A from Host B, you need to add the following routing
   item:

   route add –net 192.168.2.0 netmask 255.255.255.0 dev eth0

   Now ping Host B from Host A by typing:

   ping 192.168.4.174

   A successful ping indicates that you have created a VPN system that only allows authorized
   users from one internal network to access users at the remote site. For this system, all data is
   transmitted by UDP packets on port 5000 between OpenVPN peers.

7. To shut down OpenVPN programs, type the command:

   # killall -TERM openvpn
Setup 2: Ethernet Bridging for Private Networks on the Same Subnet

1. Set up four machines as shown in the following diagram:

![Diagram of Ethernet Bridging for Private Networks on the Same Subnet]

2. The configuration procedure is almost the same as for the previous example. The only difference is that you will need to comment out the parameter “up” in “/etc/openvpn/A-tap0-br.conf” and “/etc/openvpn/B-tap0-br.conf”.

Setup 3: Routed IP

1. Set up four machines as shown in the following diagram:

![Diagram of Routed IP]

2. Create a configuration file named “A-tun.conf” and an executable script file named “A-tun.sh”.

```bash
# point to the peer
remote 192.168.8.174
dev tun
secret /etc/openvpn/secrouter.key
cipher DES-EDE3-CBC
auth MD5
tun-mtu 1500
tun-mtu-extra 64
ping 40
ifconfig 192.168.2.173 192.168.4.174
up /etc/openvpn/A-tun.sh
```
Create a configuration file named `B-tun.conf` and an executable script file named `B-tun.sh` on OpenVPN B:

```sh
remote 192.168.8.173
dev tun
secret /etc/openvpn/secrouter.key
cipher DES-EDE3-CBC
auth MD5
tun-mtu 1500
tun-mtu-extra 64
ping 40
ifconfig 192.168.4.174 192.168.2.173
up /etc/openvpn/B-tun.sh
```

Note that the parameter “ifconfig” defines the first argument as the local internal interface and the second argument as the internal interface at the remote peer.

Note that `$5` is the argument that the OpenVPN program passes to the script file. Its value is the second argument of `ifconfig` in the configuration file.

3. Check the routing table after you run the OpenVPN programs, by typing the command:

```sh
# route
```

```
+---------------------------------+---------------------------------------------------+----------+----------+----------+----------+----------+----------+
| Destination  | Gateway | Genmsk   | Flags | Metric | Ref | Use | Iface |
+--------------+---------+----------+-------+--------+-----+-----+-------+
| 192.168.4.174|         | 255.255.255.25 | UH    | 0      | 0   | 0   | tun0   |
| 192.168.4.0  | 192.168.4.174 | 255.255.255.0 | UG    | 0      | 0   | 0   | tun0   |
| 192.168.2.0  |         | 255.255.255.0 | U     | 0      | 0   | 0   | eth1   |
| 192.168.8.0  |         | 255.255.255.0 | U     | 0      | 0   | 0   | eth0   |
```
This chapter describes how to install a tool chain in the host computer that you use to develop your applications. In addition, the process of performing cross-platform development and debugging are also introduced. For clarity, the IA240/241 embedded computer is called a target computer.

The following functions are covered in this chapter:

- **Linux Tool Chain**
  - Steps for Installing the Linux Tool Chain
  - Compilation for Applications
  - On-Line Debugging with GDB
Linux Tool Chain

The Linux tool chain contains a suite of cross compilers and other tools, as well as the libraries and header files that are necessary to compile your applications. These tool chain components must be installed on your host computer (PC) running Linux. We have confirmed that the following Linux distributions can be used to install the tool chain.

Fetchcore 1 & 2.

Steps for Installing the Linux Tool Chain

The tool chain needs about 485 MB of hard disk space. To install it, follow the steps.

1. Insert the package CD into your PC and then issue the following commands:
   
   ```bash
   #mount /dev/cdrom /mnt/cdrom
   #sh /mnt/cdrom/tool-chain/linux/install.sh
   ```

2. Wait for the installation process to complete. This should take a few minutes.

3. Add the directory `:/usr/local/arm-linux/bin` to your path. You can do this for the current login by issuing the following commands:
   
   ```bash
   #export PATH="/usr/local/arm-linux/bin:$PATH"
   ```
   Alternatively, you can add the same commands to `SHOME/.bash_profile` to make it effective for all login sessions.

Compilation for Applications

To compile a simple C application, use the cross compiler instead of the regular compiler:

```bash
#arm-linux-gcc -o example -Wall -g -O2 example.c
#arm-linux-strip -s example
#arm-linux-gcc -ggdb -o example-debug example.c
```

Most of the cross compiler tools are the same as their native compiler counterparts, but with an additional prefix that specifies the target system. In the case of x86 environments, the prefix is `i386-linux-` and in the case of IA204/241 ARM boards, it is `arm-linux-`.

For example, the native C compiler is `gcc` and the cross C compiler for ARM in the IA240/241 is `arm-linux-gcc`.

The following cross compiler tools are provided:

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ar</td>
<td>Manages archives (static libraries)</td>
</tr>
<tr>
<td>as</td>
<td>Assembler</td>
</tr>
<tr>
<td>c++, g++</td>
<td>C++ compiler</td>
</tr>
<tr>
<td>cpp</td>
<td>C preprocessor</td>
</tr>
<tr>
<td>gcc</td>
<td>C compiler</td>
</tr>
<tr>
<td>gdb</td>
<td>Debugger</td>
</tr>
<tr>
<td>ld</td>
<td>Linker</td>
</tr>
<tr>
<td>nm</td>
<td>Lists symbols from object files</td>
</tr>
<tr>
<td>objcopy</td>
<td>Copies and translates object files</td>
</tr>
<tr>
<td>objdump</td>
<td>Displays information about object files</td>
</tr>
<tr>
<td>ranlib</td>
<td>Generates indexes to archives (static libraries)</td>
</tr>
<tr>
<td>readelf</td>
<td>Displays information about ELF files</td>
</tr>
</tbody>
</table>
On-Line Debugging with GDB

The tool chain also provides an on-line debugging mechanism to help you develop your program. Before performing a debugging session, add the option `--gdb` to compile the program. A debugging session runs on a client-server architecture on which the server `gdbserver` is installed int the targe computer and the client `ddd` is installed in the host computer. We’ll assumne that you have uploaded a program named `hello-debug` to the target computer and strat to debug the program.

1. Log on to the target computer and run the debugging server program.
   ```bash
   #gdbserver 192.168.4.142:2000 hello-debug
   Process hello-debug created; pid=38
   ```
   The debugging server listens for connections at network port 2000 from the network interface 192.168.4.142. The name of the program to be debugged follows these parameters. For a program requiring arguments, add the arguments behind the program name.

2. In the host computer, change the directory to where the program source resides.
   ```bash
   cd /my_work_directory/myfilesystem/testprograms
   ```

3. Execute the client program.
   ```bash
   #ddd --debugger arm-linux-gdb hello-debug &
   ```

4. Enter the following command at the GDB, DDD command prompt.
   ```bash
   Target remote 192.168.4.99:2000
   ```
   The command produces a line of output on the target console, similar to the following.
   ```bash
   ```
   192.168.4.99 is the machine’s IP address, and 2000 is the port number. You can now begin debugging in the host environment using the interface provided by DDD.

5. Set a break point on main by double clicking, or by entering `b main` on the command line.

6. Click the `cont` button.
On-Line Debugging with Insight

Insight is a graphical user interface that accompanies GDB, the GNU Debugger was written in Tcl/Tk by people working at Red Hat, Inc., and Cygnus Solutions. Red Hat was generous enough to make Insight available for public use, and continues to maintain the program.

Click on http://sources.redhat.com/insight/ for more information about using Insight, or click on Help Topics under the Help menu to read the user manual.
This chapter includes important information for programmers.

The following functions are covered in this chapter:

- Flash Memory Map
- Device API
- RTC (Real Time Clock)
- Buzzer
- WDT (Watch Dog Timer)
- UART
- DI/DO
- Make File Example
Flash Memory Map

Partition sizes are hard coded into the kernel binary. To change the partition sizes, you will need to rebuild the kernel. The flash memory map is shown in the following table.

<table>
<thead>
<tr>
<th>Address</th>
<th>Size</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00000000 – 0x0003FFFF</td>
<td>256 KB</td>
<td>Boot Loader—Read ONLY</td>
</tr>
<tr>
<td>0x00040000 – 0x0001FFFF</td>
<td>1.8 MB</td>
<td>Kernel object code—Read ONLY</td>
</tr>
<tr>
<td>0x00200000 – 0x0009FFFF</td>
<td>8 MB</td>
<td>Root file system (JFFS2)—Read ONLY</td>
</tr>
<tr>
<td>0x00A00000 – 0x000FFFFF</td>
<td>6 MB</td>
<td>User directory (JFFS2)—Read/Write</td>
</tr>
</tbody>
</table>

Mount the user file system to /mnt/usrdisk with the root file system.

NOTE

1. The default Moxa file system only enables the network and CF. It lets users recover the user file system when it fails.
2. The user file system is a complete file system. Users can create and delete directories and files (including source code and executable files) as needed.
3. Users can create the user file system on the PC host or target platform, and then copy it to the IA240/241.

Device API

The IA240/241 supports control devices with the ioctl system API. You will need to include <moxadevice.h>, and use the following ioctl function.

```c
int ioctl(int d, int request, ...);
```

Input: int d — open device node return file handle
       int request — argument in or out

Use the desktop Linux’s man page for detailed documentation:

```
#man ioctl
```

RTC (Real Time Clock)

The device node is located at /dev/rtc. The IA240/241 supports Linux standard simple RTC control. You must include <linux/rtc.h>.

1. Function: RTC_RD_TIME
   ```c
   int ioctl(fd, RTC_RD_TIME, struct rtc_time *time);
   ```
   Description: read time information from RTC. It will return the value on argument 3.

2. Function: RTC_SET_TIME
   ```c
   int ioctl(fd, RTC_SET_TIME, struct rtc_time *time);
   ```
   Description: set RTC time. Argument 3 will be passed to RTC.

Buzzer

The device node is located at /dev/console. The IA240/241 supports Linux standard buzzer control, with The IA240/241’s buzzer running at a fixed frequency of 100 Hz. You must include <sys/kd.h>.

Function: KDMKTONE

```c
ioctl(fd, KDMKTONE, unsigned int arg);
```
Description: The buzzer’s behavior is determined by the argument arg. The “high word” part of arg gives the length of time the buzzer will sound, and the “low word” part gives the frequency.

The buzzer’s on / off behavior is controlled by software. If you call the “ioctl” function, you MUST set the frequency at 100 Hz. If you use a different frequency, the system could crash.

WDT (Watch Dog Timer)

1. Introduction

The WDT works like a watch dog function. You can enable it or disable it. When the user enables WDT but the application does not acknowledge it, the system will reboot. You can set the ack time from a minimum of 50 msec to a maximum of 60 seconds.

2. How the WDT works

The sWatchDog is disabled when the system boots up. The user application can also enable ack. When the user does not ack, it will let the system reboot.

Kernel boot

....

User application running and enable user ack

....

3. The user API

The user application must include <moxadecvic.h>, and link moxalib.a. A makefile example is shown below:

```makefile
all:
  arm-linux-gcc -o xxxx xxxx.c -lmoxalib
```

```c
int swtd_open(void)
```

Description
Open the file handle to control the sWatchDog. If you want to do something you must first to this. And keep the file handle to do other.

Input
None

Output
The return value is file handle. If has some error, it will return < 0 value.

You can get error from errno().

```c
int swtd_enable(int fd, unsigned long time)
```

Description
Enable application sWatchDog. And you must do ack after this process.

Input
```
int fd     - the file handle, from the swtd_open() return value.
unsigned long time  - The time you wish to ack sWatchDog periodically. You must ack the sWatchDog before timeout. If you do not ack, the system will be reboot automatically. The
```
minimal time is 50 msec, the maximum time is 60 seconds. The time unit is msec.

**Output**
OK will be zero. The other has some error, to get the error code from errno().

```c
int swtd_disable(int fd)
```

**Description**
Disable the application to ack sWatchDog. And the kernel will be auto ack it. User does not to do it at periodic.

**Input**
int fd - the file handle from swtd_open() return value.

**Output**
OK will be zero. The other has some error, to get error code from errno.

```c
int swtd_get(int fd, int *mode, unsigned long *time)
```

**Description**
Get current setting values.

mode –
1 for user application enable sWatchDog: need to do ack.
0 for user application disable sWatchdog: does not need to do ack.

time – The time period to ack sWatchDog.

**Input**:
int fd - the file handle from swtd_open() return value.
int *mode - the function will be return the status enable or disable user application need to do ack.
unsigned long *time – the function will return the current time period.

**Output:**
OK will be zero.
The other has some error, to get error code from errno().

```c
int swtd_ack(int fd)
```

**Description**
Acknowledge sWatchDog. When the user application enable sWatchDog. It need to call this function periodically with user predefined time in the application program.

**Input**
int fd - the file handle from swtd_open() return value.

**Output**
OK will be zero.
The other has some error, to get error code from errno().

```c
int swtd_close(int fd)
```

**Description**
Close the file handle.
**Input**

int fd - the file handle from swtd_open() return value.

**Output**

OK will be zero.

The other has some error, to get error code from errno().

4. **Special Note**

When you “kill the application with -9” or “kill without option” or “Ctrl+c” the kernel will change to auto ack the sWatchDog.

When your application enables the sWatchDog and does not ack, your application may have a logical error, or your application has made a core dump. The kernel will not change to auto ack. This can cause a serious problem, causing your system to reboot again and again.

5. **User application example**

**Example 1:**

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <moxadevice.h>

int main(int argc, char *argv[]) {
    int fd;

    fd = swtd_open();
    if ( fd < 0 ) {
        printf("Open sWatchDog device fail !\n");
        exit(1);
    }
    swtd_enable(fd, 5000); // enable it and set it 5 seconds
    while ( 1 ) {
        // do user application want to do
        ....
        swtd_ack(fd);
        ....
    }
    swtd_close(fd);
    exit(0);
}
```

The makefile is shown below:

```
all:
    arm-linux-gcc -o xxxx xxxx.c -lmoxalib
```

**Example 2:**

```c
#include <stdio.h>
#include <stdlib.h>
#include <signal.h>
#include <string.h>
#include <sys/stat.h>
#include <sys/ioctl.h>
#include <sys/select.h>
#include <sys/time.h>
#include <moxadevice.h>
```
static void mydelay(unsigned long msec)
{
    struct timeval time;
    time.tv_sec = msec / 1000;
    time.tv_usec = (msec % 1000) * 1000;
    select(1, NULL, NULL, NULL, &time);
}

static int swtdfd;
static int stopflag=0;

static void stop_swatchdog()
{
    stopflag = 1;
}

static void do_swatchdog(void)
{
    swtd_enable(swtdfd, 500);
    while ( stopflag == 0 ) {
        mydelay(250);
        swtd_ack(swtdfd);
    }
    swtd_disable(swtdfd);
}

int main(int argc, char *argv[])
{
    pid_t sonpid;

    signal(SIGUSR1, stop_swatchdog);
    swtdfd = swtd_open();
    if ( swtdfd < 0 ) {
        printf("Open sWatchDog device fail !\n");
        exit(1);
    }
    if ( (sonpid=fork()) == 0 )
        do_swatchdog();
    // do user application main function
    ....
    /* end user application
    kill(sonpid, SIGUSR1);
    swtd_close(swtdfd);
    exit(1);
    */
}

The makefile is shown below:

all:
    arm-linux-gcc -o xxxx xxxx.o -lmoxalib
UART

The normal tty device node is located at `/dev/ttyM0` ... `ttyM3`.

The IA240/241 supports Linux standard termios control. The Moxa UART Device API allows you to configure ttyM0 to ttyM3 as RS-232, RS-422, 4-wire RS-485, or 2-wire RS-485. IA240/241 supports RS-232, RS-422, 2-wire RS-485, and 4-wire RS485.

You must include `<moxadevice.h>`.

```c
#define RS232_MODE   0
#define RS485_2WIRE_MODE  1
#define RS422_MODE   2
#define RS485_4WIRE_MODE  3
```

1. **Function:** Moxa_SET_OP_MODE
   ```c
   int ioctl(fd, MOXA_SET_OP_MODE, &mode)
   ```
   **Description**
   Set the interface mode. Argument 3 mode will pass to the UART device driver and change it.

2. **Function:** MOXA_GET_OP_MODE
   ```c
   int ioctl(fd, MOXA_GET_OP_MODE, &mode)
   ```
   **Description**
   Get the interface mode. Argument 3 mode will return the interface mode.

There are two Moxa private ioctl commands for setting up special baudrates.

**Function:** MOXA_SET_SPECIAL_BAUD_RATE
**Function:** MOXA_GET_SPECIAL_BAUD_RATE

If you use this ioctl to set a special baudrate, the termios `cflag` will be B4000000, in which case the `B4000000` define will be different. If the baudrate you get from `termios` (or from calling `tcgetattr()`) is B4000000, you must call `ioctl` with `MOXA_GET_SPECIAL_BAUD_RATE` to get the actual baudrate.

**Example to set the baudrate**
```c
#include <moxadevice.h>
#include <termios.h>
struct termios term;
int fd, speed;
fd = open("/dev/ttyM0", O_RDWR);
tcgetattr(fd, &term);
term.c_cflag &= ~(CBAUD | CBAUDEX);
term.c_cflag |= B4000000;
tcsetattr(fd, TCSANOW, &term);
speed = 500000;
ioctl(fd, MOXA_SET_SPECIAL_BAUD_RATE, &speed);
```

**Example to get the baudrate**
```c
#include <moxadevice.h>
#include <termios.h>
struct termios term;
int fd, speed;
fd = open("/dev/ttyM0", O_RDWR);
tcgetattr(fd, &term);
if ( (term.c_cflag & (CBAUD|CBAUDEX)) != B4000000 ) {
    // follow the standard termios baud rate define
} else {
    ioctl(fd, MOXA_GET_SPECIAL_BAUD_RATE, &speed);
}
### Baudrate inaccuracy

Divisor = 921600/Target Baud Rate. (Only Integer part)

\[ \text{ENUM} = 8 \times \left( \frac{921600}{\text{Target Baud Rate}} \right) \text{ (Round up or down)} \]

\[ \text{Inaccuracy} = \left( \frac{\text{Target Baud Rate} - \frac{921600}{\text{Divisor} + \left( \frac{\text{ENUM}}{8} \right)}}{\text{Target Baud Rate}} \right) \times 100\% \]

E.g.,

To calculate 500000 bps

Divisor = 1, ENUM = 7,

Inaccuracy = 1.7%

*The Inaccuracy should less than 2% for work reliably.

### Special Note

1. If the target baudrate is not a special baudrate (e.g. 50, 75, 110, 134, 150, 200, 300, 600, 1200, 1800, 2400, 4800, 9600, 19200, 38400, 57600, 115200, 230400, 460800, 921600), the termios cflag will be set to the same flag.

2. If you use stty to get the serial information, you will get speed equal to 0.

### DI/DO

**int set_dout_state(int doport, int state)**

**Description**

Set the digital output state to high or low.

**Input**

- int doport - the digital output port number. It is 0 to 3.
- int state - the output state, high or low. You can use define DIO_HIGH or DIO_LOW.

**Output**

OK will be zero.

**int get_din_state(int diport, int *state)**

**Description**

Get the digital input current state at now.

**Input**

- int diport - the digital input port number. It is 0 to 3.
- int *state - To save the digital input state at now.

**Output**

OK will be zero.

**int get_dout_state(int doport, int *state)**

**Description**

Get the digital output current state at now.

**Input**

- int doport - the digital output port number. It is 0 to 3.
- int *state - To save the digital output state at now.

**Output**

OK will be zero.
int set_din_event(int diport, void (*func)(int diport), int mode, long int duration)

Description
Set the callback function for digital input port when the state is changed from high to low, low to high or any sate changed.

Input
int diport  - the digital output port number. It is 0 to 3.
void (*func)(int diport)  - The call back function point. It will be called when the set event happens.
int mode  - Set the kind event. High to low, low to high or both.
long int duration - We know the digital signal sometime is not reliable. You can the duration time to except the error signal. If you set to zero, it will not detect the duration time. You can set 40 ms to 3600000 ms by increase 20 ms.

Output
OK will be zero.

int get_din_event(int diport, int *mode, long int *duration)

Description
Get the set event for digital input port.

Input
int diport  - the digital output port number. It is 0 to 3.
int *mode  - Save the set event.
long int *duration - Save the set duration time value.

Output
OK will be zero.

Special Note
Don’t forget to link the library libmoxalib & libpthread for DI/DO programming, and also include the header file moxadevice.h. The DI/DO library only can be used by one program at a time.

Example
Example 1

File Name: tdio.c

Description: The program indicates to connect DO1 to DI1, change the digital output state to high or low by manual input, then the detect and count the state changed events from DI1.(OK)

```c
#include <stdio.h>
#include <stdlib.h>
#include <moxadevice.h>
#include <fcntl.h>

#ifdef DEBUG
#define dbg_printf(x...) printf(x)
#else
#define dbg_printf(x...)
#endif

#define MIN_DURATION 40

static char *DataString[2] = {"Low ", "High "};
static void hightolowevent(int diport)
{
    printf("DIN port %d high to low.\n", diport);
}
static void lowtohighevent(int diport)
{
    printf("DIN port %d low to high.\n", diport);
}

int main(int argc, char * argv[])
{
    int i, j, state, retval;
    unsigned long duration;

    while( 1 ) {
        printf("Select a number of menu, other key to exit.\n")
        1. set high to low event \n
        2. get now data. \n
        3. set low to high event \n
        4. clear event \n
        5. set high data. \n
        6. set low data. \n
        7. quit \n
        8. show event and duration \n
        Choose : ");
        retval =0;
        scanf("%d", &i);   
        if ( i == 1 ) { // set high to low event

“Software Lock” is an innovative technology developed by the Moxa engineering force. It can be adopted by a system integrator or developer to protect his applications from being copied. An application is compiled into a binary format bound to the embedded computer and the operating system (OS) that the application runs on. As long as one obtains it from the computer, he/she can install it into the same hardware and the same operating system. The add-on value created by the developer is thus lost.

Moxa engineering force has developed this protection mechanism for your applications via data encryption. The binary file associated with each of your applications needs to undergo an additional encryption process after you have developed it. The process requires you to install an encryption key in the target computer.

1. Choose an encryption key (e.g., "ABigKey") and install it in the target computer by a pre-utility program, ‘setkey’.

   #setkey ABigKey

   Note: set an empty string to clear the encryption key in the target computer by:

   #setkey ""

2. Develop and compile your program in the development PC.

3. In the development PC, run the utility program ‘binencryptor’ to encrypt your program with an encryption key.

   #binencryptor yourProgram ABigKey

4. Upload the encrypted program file to the target computer by FTP or NFS and test the program. The encryption key is a computer-wise key. That is to say, a computer has only one key installed. Running the program ‘setkey’ multiple times causes the key to be overridden.

   To prove the effectiveness of this software protection mechanism, prepare a target computer that has not been installed an encryption key or install a key different from that used to encrypt your program. In any case, the encrypted program fails immediately.

   This mechanism also allows the computer with an encryption key to bypass programs that are not encrypted. Therefore, in the development phase, you can develop your programs and test them in the target computer cleanly.
Linux normal command utility collection

File manager

1. **cp**  copy file
2. **ls**  list file
3. **ln**  make symbolic link file
4. **mount**  mount and check file system
5. **rm**  delete file
6. **chmod**  change file owner & group & user
7. **chown**  change file owner
8. **chgrp**  change file group
9. **sync**  sync file system, let system file buffer be saved to hardware
10. **mv**  move file
11. **pwd**  display now file directly
12. **df**  list now file system space
13. **mkdir**  make new directory
14. **rmdir**  delete directory

Editor

1. **vi**  text editor
2. **cat**  dump file context
3. **zcat**  compress or expand files
4. **grep**  search string on file
5. **cut**  get string on file
6. **find**  find file where are there
7. **more**  dump file by one page
8. **test**  test file exist or not
9. **sleep**  sleep (seconds)
10. **echo**  echo string

Network

1. **ping**  ping to test network
2. **route**  routing table manager
3. **netstat**  display network status
4. **ifconfig**  set network ip address
5. **tracerout**  trace route
6. **tftp**
7. **telnet**
8. **ftp**
Process
1. kill  kill process
2. ps    display now running process

Other
1. dmesg dump kernel log message
2. sty   to set serial port
3. zcat  dump .gz file context
4. mknod make device node
5. free  display system memory usage
6. date  print or set the system date and time
7. env   run a program in a modified environment
8. clear clear the terminal screen
9. reboot reboot / power off/on the server
10. halt  halt the server
11. du    estimate file space usage
12. gzip, gunzip compress or expand files
13. hostname show system’s host name

Moxa special utilities
1. kversion show kernel version
2. cat /etc/version show user directory version
3. upramdisk mount ramdisk
4. downramdisk unmount ramdisk
